1 Executive Summary

Dear all,

Thank you for trusting us to help SparkDAO with this security audit. Our executive summary provides an overview of subjects covered in our audit of the latest reviewed contracts of Spark ALM Controller according to Scope to support you in forming an opinion on their security risks.

SparkDAO implements the Spark ALM Controller, a suite of contracts of the Spark Liquidity Layer designed to manage and control the flow of liquidity originating from DSS Allocator. This latest iteration reviewed added support for Arbitrary ERC-4626 vaults, Aave and Ethena.

The most critical subjects covered in our audit are functional correctness, access control, and the integration with 3rd-party protocols. The general subjects covered are gas efficiency, documentation and composability.

Security regarding all the aforementioned subjects is high.

It is important to note that security audits are time-boxed and cannot uncover all vulnerabilities. They complement but don't replace other vital measures to secure a project.

The following sections will give an overview of the system, our methodology, the issues uncovered, and how they have been addressed. We are happy to receive questions and feedback to improve our service.

Sincerely yours,

ChainSecurity

1.1 Overview of the Findings

Below we provide a brief numerical overview of the findings and how they have been addressed.

Critical-Severity Findings		0
High-Severity Findings		0
Medium-Severity Findings		0
Low-Severity Findings		3
• Code Corrected		1
• Risk Accepted		1
• Acknowledged		1

2 Assessment Overview

In this section, we briefly describe the overall structure and scope of the engagement, including the code commit which is referenced throughout this report.

2.1 Scope

The assessment was performed on the source code files inside the Spark ALM Controller repository based on the documentation files. The table below indicates the code versions relevant to this report and when they were received.

V	Date	Commit Hash	Note
1	15 Sep 2024	7a0535ee07815a2c8604d58469393c56a62 d5b81	Initial Version
2	26 Sep 2024	2087250fc5988d3f0117f23e3f959f9423d04 909	Second Version
3	03 Oct 2024	c76b422b053dd055aeb2cd555acfe353f05b 316e	Fixes And Deployment Scripts
4	07 0ct 2024	342fe537b020ffa8ea7fcedf166b59b7ede21 232	Fix Deployment Scripts
5	08 0ct 2024	52deda866ec8abdeaae9ace8574457d3e42 09c36	Setting USDS And sUSDS Rate Limits
6	22 Oct 2024	6058f68f79520eb06ea8eded146da13039c 47525	Bump Version
7	29 Nov 2024	f81a7366f339d806a07a992c3aef2afe9a06 3e13	Aave & Ethena Integration
8	06 Dec 2024	ad4391c37aa262d3c578a757700c1b6e86a 96060	Withdrawals Rate Limit
9	13 Dec 2024	2bb2680893aa3e42210c8f907ec4d5778ac e9fe6	Final Release

For the solidity smart contracts, the compiler version 0.8.21 was chosen with the evm version set to shanghai.

The files in scope were:

```
aLMProxy.sol
    ForeignController.sol
    MainnetController.sol
    RateLimitHelpers.sol
    RateLimits.sol
    interfaces/
        IALMProxy.sol
        IRateLimits.sol
        CCTPInterfaces.sol
```

In (Version 3) the following files were further added to scope:

deploy/
 ControllerDeploy.sol
 ControllerInit.sol
 ControllerInstance.sol

2.1.1 Excluded from scope

All other files are out of scope. It is assumed that USDC and CCTP will work honestly as documented.

In addition, the inherent centralization risks of USDC are out of the scope of this review:

- USDC is deployed behind a proxy, and its implementation can be upgraded by an admin.
- CCTP relies on a set of centralized offchain signers to provide the bridging attestation.

All other 3rd-party protocols that the ALMProxy interacts with, especially Aave and Ethena (added in version 7), are out of scope and assumed to work correctly as documented.

Note that the deployment script is in scope. However, governance should validate the deployment.

2.2 System Overview

This system overview describes the initially received version (Version 1) of the contracts as defined in the Assessment Overview.

At the end of this report section, we have added subsections for each of the changes according to the versions.

Furthermore, in the findings section, we have added a version icon to each of the findings to increase the readability of the report.

SparkDAO offers Spark ALM Controller, a set of on-chain components of the Spark Liquidity Layer designed to manage and control the flow of liquidity between Ethereum mainnet and L2s by leveraging DSS Allocator.

On each chain, the following contracts are deployed:

- 1. ALMProxy: Entity that holds funds and interacts with external contracts (e.g. DssAllocator, PSM). Thus, it holds the required privileges to interact with other contracts.
- 2. Controllers: Dictate which operations an ALMProxy shall perform. Note that multiple controllers could point to the same ALMProxy.
- 3. RateLimits: Computes limits for liquidity flows.

All of the contracts inherit the standard AccessControl and grant the DEFAULT_ADMIN_ROLE role to an admin which can configure other roles.

2.2.1 ALMProxy

The ALMProxy provides the following privileged functions that are restricted to addresses with the CONTROLLER role:

- 1. doCall(): triggers a call from ALMProxy to a target contract with msg.value.
- 2. doCallWithValue(): triggers a call from ALMProxy to a target contract with a specific value.
- 3. doDelegateCall(): triggers a delegatecall from ALMProxy to a target contract.

2.2.2 Controllers

MainnetController defines operations in the context of the mainnet ALMProxy that are restricted to addresses with the RELAYER role:

- 1. mintUSDS() / burnUSDS(): leverages AllocatorVault to mint or burn (draw() or wipe()) USDS.
- 2. depositToSUSDS() / withdrawFromSUSDS(): wraps USDS to SUSDS or vice-versa.
- 3. redeemFromSUSDS(): this further provides the option to unwrap SUSDS by specifying the shares to burn.
- 4. swapUSDSToUSDC() / swapUSDCToUSDS(): leverages the PSM to swap between USDS and USDC without fees (buyGemNoFee and sellGemNoFee).
- 5. transferUSDCToCCTP(): leverages CCTP (Circle's Cross-Chain Transfer Protocol) to bridge USDC to a recipient (expected to be another ALMProxy) on a foreign domain.

ForeignController defines operations in the context of a foreign domain ALMProxy that are restricted to addresses with the RELAYER role:

- 1. depositPSM() / withdrawPSM(): deposits / withdraws specific assets to / from Spark PSM.
- 2. transferUSDCToCCTP(): leverages CCTP (Circle's Cross-Chain Transfer Protocol) to bridge USDC to a recipient (expected to be another ALMProxy) on a foreign domain.

Both controller types provide the following administrative functions:

- 1. freeze(): restricted to the FREEZER role to pause all the operations defined above.
- 2. reactivate(): restricted to the DEFAULT_ADMIN_ROLE to reactivate the operations.
- 3. setMintRecipient(): set the token recipient of a destination domain when bridging USDC with CCTP.

In addition, except interaction with SUSDS, all other operations are subject to specific limits defined by Rate Limits.

2.2.3 Rate Limits

RateLimits defines a limit on a rate for a given key. The rate limit will linearly grow from lastAmount with slope over the time elapsed (tracked with lastUpdated), and is capped maxAmount. The full rate limit data or the current rate limit can be queried from getRateLimitData() and getCurrentRateLimit(), respectively.

The data can be set by the DEFAULT_ADMIN_ROLE with setRateLimitData() (two signatures available) or setUnlimitedRateLimitData().

The following functions are introduced to update the rate limit by the CONTROLLER role:

- 1. triggerRateLimitDecrease(): It deducts an amount from the current rate limit and sets lastUpdated to block.timestamp. In case of the rate limit is insufficient, the call will revert.
- 2. triggerRateLimitIncrease(): It adds an amount to the current rate limit (capped by the maxAmount) and sets lastUpdated to block.timestamp.

2.2.4 Deployment Scripts

In version 3 (see Changes in Version 3), deployment scripts have been added that can be used in governance spells.

MainnetControllerDeploy and ForeignControllerDeploy libraries both offer the functions deployController and deployFull to deploy on mainnet and on the foreign chain, respectively. While deployController solely deploys a controller with a given ALM proxy and rate limit contract, the deployFull function deploys the ALM proxy and rate limit contract as well.

The MainnetControllerInit library implements functionality to initialize the ALM controller architecture on mainnet. Three functions are offered:

- 1. subDaoInitController: For SubDAO. Sanity checks along with assigning the expected roles and setting rate limits for the expected keys. Additionally, allows to revoke the roles of a previously used controller contract.
- 2. subDaoInitFull: For SubDAO. subDaoInitController with additional sanity checks on the ALM proxy and the rate limit contract along with setting the required access control on the allocator infrastructure.
- 3. pauseProxyInit: For Sky Governance. Calls kiss on the PSM to allow fee-less swaps on the PSM. Note that no checks are performed. Thus, this should be performed only after the expected spell to setup the ALM controller have been performed by the SubDAO.

Note that the current version of the mainnet controller will be only able to use CCTP to bridge to Base.

The ForeignControllerInit library implements functionality to initialize the ALM controller architecture on a foreign chain (at the time of writing: Base). Only init is offered. Essentially it performs similar actions to subDaoInitFull in the MainnetControllerInit. However, customized to the ForeignController contract. Note that only USDC will be usable in the integration with the Spark PSM on L2.

Note that L1 addresses are not published to the Chainlog (which is intended).

2.2.5 Changes in Version 2

The changes below were introduced in version 2 of the codebase:

- 1. The transferUSDCToCCTP function now has an additional limit on the amount of USDC that can be bridged to a given domain.
- 2. The MainnetController's swapUSDCToUSDS function now uses the PSM's fill function to allow filling the PSM if needed. As a consequence, swaps will be repeated as long as the full USDC amount has not been swapped (with filling happening before the swap). In case the USDC amount cannot be swapped, a revert will occur as before.
- 3. The unused immutables usds and susds have been removed from the ForeignController, hence these two addresses cannot be queried from the controller anymore.

2.2.6 Changes in Version 3

The following changes were introduced in version 3 of the codebase:

- 1. Function receive() has been added to the ALMProxy to support receiving ETH.
- 2. Events will be emitted when changing the controller's active status and setting the mint recipient on a destination domain.
- 3. Deployment scripts have been included in scope, see Deployment Scripts.

2.2.7 Changes in Version 4

Now, on the foreign controller's initialization, limits for USDS and sUSDS are set up for PSM deposits and withdrawals.

2.2.8 Changes in Version 7

In this version, the integration with any ERC-4626 compliant vault, Aave V3, and Ethena was added. These interactions can only be triggered by the relayer when the controller is active.

For the ERC-4626 compliant vault and Aave V3 integration in the MainnetController and ForeignController:

- The relayer can deposit into any ERC-4626 vault with depositERC4626() respecting the respective rate limit on each vault, the minted shares will be credited to the ALMProxy. The relayer can also withdraw from any ERC-4626 vault with withdrawERC4626() or redeemERC4626() without any rate limit. The sUSDS related interactions can be achieved with these ERC-4626 functions, hence they are removed.
- The relayer can also deposit into Aave with depositAave() respecting the aToken dependent rate, and the newly minted aToken will be credited to the ALMProxy. The relayer can also withdraw any underlying asset of an aToken from Aave with withdrawAave() without any rate limit.

For Ethena USDe and sUSDe integration in the MainnetController:

- The relayer can configure any amount of delegated signers for the ALMProxy with setDelegatedSigner() and removeDelegatedSigner(). The assigned delegated signers must explicitly accept the delegation with confirmDelegatedSigner() on Ethena before they can sign any Order on behalf of the ALMProxy. An Order is an expirable intent to mint or redeem USDe with fixed spending collateral and outcome USDe.
- In addition, it requires a minter and burner role on Ethena minting contract to submit the tx with the Order and signature prepared by the delegated signers.
- The relayers can only prepareUSDeMint() and prepareUSDeBurn() by triggering an approval from the ALMProxy to the Ethena minting contract. Further operations from the delegated signers, Ethena minter and burners are required to complete the action.
- Once the ALMProxy obtained USDe, it can be deposited into sUSDe to earn an interest. The deposit into sUSDe follows the typical ERC-4626 deposit interface.
- The instant withdrawal of sUSDe is blocked currently, which requires a cooldown period followed by an unstake() call. The relayer can trigger the cooldown with cooldownAssetsSUSDe() or cooldownSharesSUSDe(), which burned the shares and credited the USDe to the USDeSilo contract. Once the cooldownDuration is reached, the relayer can trigger the exit of USDe to the ALMProxy with unstake().

2.2.9 Changes in Version 8

In this version withdrawal rate limits for ERC-4626 and Aave have been added. Hence the ALMProxy will only interact with authorized ERC-4626 and Aave aTokens with limited rates.

2.2.10 Roles & Trust Model

ALMProxy: The admin is fully trusted, otherwise, it can setup controllers and trigger any calls with the privilege of ALMProxy. The CONTROLLER is also trusted.

In addition, the ALMProxy requires several roles to operate, which are assumed to be setup properly by governance, for instance:

- 1. It requires bud role to swap without fee on DssPSMLite.
- 2. It requires wards role on AllocatorVault to draw() and wipe() USDS.
- 3. It needs sufficient allowance from AllocatorBuffer to move minted USDS.

MainnetController and ForeignController: The admin is fully trusted, otherwise they can DoS the Controller, or steal the bridged money on the destination domain by changing the mint recipient. The RELAYER is semi-trusted, and they can only change the liquidity allocation in the worst case. The FREEZER is also semi-trusted which can temporarily DoS the Controller in the worst case.

As of version 3, deployments scripts are in scope. Before initializing the contracts, governance should always carefully examine whether the deployed contracts match the expectations.

RateLimits: The admin is fully trusted to configure the limit data and CONTROLLER correctly.

As of version 7, the integration with arbitrary ERC-4626, Aave, and Ethena requires an extended trust model. Generally the third party protocols receiving funds are assumed to be non-malicious.

Arbitrary ERC-4626: The admin should only configure a deposit rate limit for trusted external ERC-4626 vaults.

Aave: Aave governance can adjust the parameters for the reserves such as setting it inactive, paused or frozen or upgrading the pool / aToken implementations. Spark ALM Controller is subject to the potential risks of Aave, and Aave governance is fully trusted to not misbehave.

Ethena: The funds deposited to Ethena are subject to the risks of depegging and minting / burning limits of Ethena. The minter and burner of USDe are fully trusted, otherwise, they can DoS the USDe minting and burning. The delegated signers assigned by relayers are semi-trusted:

- 1. There could be a race condition if multiple delegated signers exist, who can sign orders with different volume and quotes.
- 2. The signers may not sign any order or not use all the allowance prepared by the ALMProxy.
- 3. The signers can sign with bad quotes regardless of the ones Ethena returned. It is assumed the fully trusted Ethena minter / redeemer will never submit these malicious orders. (see A Compromised Ethena Minter Or Redeemer May Execute A Bad Order)

Semi-trusted roles are expected to operate honestly but may be compromised. They must not be able to gain control over funds or exit funds from the system. While they may continue actions until replaced, all funds must remain under the ALMproxy's control.

Holding sUSDe further implies the risks of blacklisting (for deposit / withdraw / transfer) and confiscating, the admins and other privileged roles of sUSDe are trusted to not misbehave.

The relayers are semi trusted, a compromised Relayer Can DoS SUSDE Unstaking, which requires admin privilege to remove the malicious relayer. In addition, as a relayer can assign any delegated signer, a compromised relayer can incur all the aforementioned risks of a malicious delegated signer.

In addition, it is assumed Spark ALM Controller will not interact with weird ERC-20 (rebasing / low decimals / ...) and ERC-4626 vault (low token decimals / without share inflation protection / ...). Otherwise, for instance, in case an ERC-4626 has low decimals, a relayer may amplify the loss due to rounding errors in shares conversion with many calls for ALMProxy on L2s.

3 Limitations and use of report

Security assessments cannot uncover all existing vulnerabilities; even an assessment in which no vulnerabilities are found is not a guarantee of a secure system. However, code assessments enable the discovery of vulnerabilities that were overlooked during development and areas where additional security measures are necessary. In most cases, applications are either fully protected against a certain type of attack, or they are completely unprotected against it. Some of the issues may affect the entire application, while some lack protection only in certain areas. This is why we carry out a source code assessment aimed at determining all locations that need to be fixed. Within the customer-determined time frame, ChainSecurity has performed an assessment in order to discover as many vulnerabilities as possible.

The focus of our assessment was limited to the code parts defined in the engagement letter. We assessed whether the project follows the provided specifications. These assessments are based on the provided threat model and trust assumptions. We draw attention to the fact that due to inherent limitations in any software development process and software product, an inherent risk exists that even major failures or malfunctions can remain undetected. Further uncertainties exist in any software product or application used during the development, which itself cannot be free from any error or failures. These preconditions can have an impact on the system's code and/or functions and/or operation. We did not assess the underlying third-party infrastructure which adds further inherent risks as we rely on the correct execution of the included third-party technology stack itself. Report readers should also take into account that over the life cycle of any software, changes to the product itself or to the environment in which it is operated can have an impact leading to operational behaviors other than those initially determined in the business specification.

4 Terminology

For the purpose of this assessment, we adopt the following terminology. To classify the severity of our findings, we determine the likelihood and impact (according to the CVSS risk rating methodology).

- Likelihood represents the likelihood of a finding to be triggered or exploited in practice
- Impact specifies the technical and business-related consequences of a finding
- · Severity is derived based on the likelihood and the impact

We categorize the findings into four distinct categories, depending on their severity. These severities are derived from the likelihood and the impact using the following table, following a standard risk assessment procedure.

Likelihood	Impact		
	High	Medium	Low
High	Critical	High	Medium
Medium	High	Medium	Low
Low	Medium	Low	Low

As seen in the table above, findings that have both a high likelihood and a high impact are classified as critical. Intuitively, such findings are likely to be triggered and cause significant disruption. Overall, the severity correlates with the associated risk. However, every finding's risk should always be closely checked, regardless of severity.

5 Findings

In this section, we describe any open findings. Findings that have been resolved have been moved to the Resolved Findings section. The findings are split into these different categories:

- Security: Related to vulnerabilities that could be exploited by malicious actors
- Design: Architectural shortcomings and design inefficiencies

Below we provide a numerical overview of the identified findings, split up by their severity.

Critical -Severity Findings	0
High-Severity Findings	0
Medium-Severity Findings	0
Low-Severity Findings	2

- Freeze Cannot Revoke the Unused Approval (Acknowledged)
- Relayer Can DoS SUSDE Unstaking Risk Accepted

5.1 Freeze Cannot Revoke the Unused Approval

CS-SPRKALM-008

The privileged role FREEZER can pause the MainnetController with freeze(), which prevents the relayers from triggering any more interactions or funds transfers from the ALMProxy.

However, since the Ethena integration requires actions from several external parties (see Allowance For Ethena Minter May Not Be Consumed), the actual transfers of underlying assets to mint or redeem USDe may happen even after the MainnetController is frozen.

In summary, after the MainnetController is frozen, any unused approval for the Ethena minter contract can still be used which modifies the balance of ALMProxy.

Acknowledged:

SparkDAO acknowledged the issue and decide not to change the code since Ethena is fully trusted.

5.2 Relayer Can DoS SUSDE Unstaking

CS-SPRKALM-009

In Ethena, two steps are required to convert sUSDe to USDe:

- A cooldown must be initiated first, which (1) burns the shares and credit the USDe to the USDeSilo contract (2) reset the cooldownEnd to be cooldownDuration from current block.timestamp. Note the step (2) will extend any existing cooldown asset to another cooldownDuration.
- When the cooldownEnd is reached, the sUSDe can be unstaked and the USDe will be credited to a specified receiver.

Consequently, a malicious relay can keep triggering new cooldowns with as less as 1 wei asset to block previous exits from sUSDe to USDe, hence DoS the sUSDe to USDe conversion.

Note: SparkDAO was aware of this issue and had reported to us before the audit. In addition, in case a malicious relayer DoSed the sUSDe unstake(), SparkDAO will freeze the controller, remove the malicious relayer, and reactivate the controller again.

Resolved Findings 6

Here, we list findings that have been resolved during the course of the engagement. Their categories are explained in the Findings section.

Below we provide a numerical overview of the identified findings, split up by their severity.

Critical - Severity Findings	0
High-Severity Findings	0
Medium-Severity Findings	0
Low-Severity Findings	1
Loosely Restricted Specific Calls to Arbitrary Address	

Mint Recipient Is Not Initialized Code Corrected

- Sanity Checks In Deployment Scripts Code Corrected
- Unused Parameters Code Corrected
- ALM Proxy Cannot Receive Code Corrected
- Constructor Parameters Code Corrected
- Events Code Corrected

Informational Findings

Loosely Restricted Specific Calls to Arbitrary Address

CS-SPRKALM-012

6

ERC4626 Integration: The integrator can freely trigger calls (respecting the ERC-4626 withdraw and redeem interfaces) from the ALMProxy to arbitrary addresses.

Aave Integration: The integrator can freely call withdrawAave() for any aToken and amount without any rate limit. In addition, since the Aave pool address is fetched from the aToken instead of being hardcoded, the ALMProxy may eventually call an arbitrary contract with the Aave pool withdraw interface.

These calls are loosely restricted and could be unexpected if there is a function selector collision on contracts where ALMProxy has privileges.

Code corrected:

Withdrawal rate limits have been added to the withdraw / redeem logic of ERC-4626 and Aave's withdraw logic.

Mint Recipient Is Not Initialized

Informational Version 3 Code Corrected

In the controller initialization library, the RateLimit of bridging tokens with CCTP has been configured, however, the mint recipients are not. As a result, USDC cannot be bridged after initialization and another spell is required to set the mint recipients.

Code corrected:

Mint recipients are now configured in the initialization library.

6.3 Sanity Checks In Deployment Scripts

Informational Version 3 Code Corrected

CS-SPRKALM-005

- 1. The initialization code doesn't check if the Foreign Controller is active.
- 2. The status of the Spark PSM is not validated in the Foreign Controller intialization library. The Spark ALM would be subjected to Share Inflation Attack if the deployer of Spark PSM does not make the proper first deposit.
- 3. In the initialization library for both the Mainnet and Foreign controllers, there is no validation to ensure that the new controller address (controllerInst.controller) is different from the old controller address (params.oldController). If both addresses are the same, the script will first grant the necessary permissions to the controller and then immediately revoke them. As a result, the controller address will not obtain the CONTROLLER role.

Code corrected:

Code has been corrected to perform the respective checks.

6.4 Unused Parameters

Informational Version 3 Code Corrected

CS-SPRKALM-006

The intialization function <code>init()</code> of the Foreign Controller takes as parameters <code>params.usds</code> and <code>params.susds</code>. However, these parameters are not used in the function.

Code corrected:

Code has been corrected by removing usds and susds from the AddressParams struct.

6.5 ALM Proxy Cannot Receive

Informational Version 1 Code Corrected

CS-SPRKALM-001

The ALM proxy contract is intended to be used for use-cases beyond the implementations of the current controllers. In the future, scenarios might exist where a controller requires that the proxy can receive ETH

(e.g. by withdrawing from WETH). However, such use cases are not possible to implement due to the lack of a receive function.

Code corrected:

Function receive() has been added to support receiving ETH.

6.6 Constructor Parameters

Informational Version 1 Code Corrected

CS-SPRKALM-002

The constructor of the mainnet controller receives <code>buffer</code> as an input. However, the <code>buffer</code> could be retrieved from the <code>vault</code>. Ultimately, retrieving the buffer on-chain could make the code more consistent (e.g. <code>dai</code> is retrieved from <code>daiUsds</code>).

Code corrected:

Code has been corrected to retrieve buffer from the vault.

6.7 Events

Informational Version 1 Code Corrected

CS-SPRKALM-003

The controller contracts lack events on important state changes. More specifically no event is emitted on

- 1. setMintRecipient()
- 2. freeze()
- 3. reactivate()

which involve important state changes.

For other functions, such as MainnetController::mintUSDS no event is emitted. Note that the relevant events can be retrieved from the external contracts. However, that is also true for CCTP which emits DepositForBurn making CCTPTransferInitiated redundant. Nevertheless, emitting an event on every action could also be reasonable to easily allow distinguishing which controller (of the potentially many) initiated a certain sequence of calls.

Code corrected:

The following events have been added to the privileged functions in both mainnet and foreign controllers:

- 1. event Frozen.
- 2. event MintRecipientSet.
- 3. event Reactivated.

7 Informational

We utilize this section to point out informational findings that are less severe than issues. These informational issues allow us to point out more theoretical findings. Their explanation hopefully improves the overall understanding of the project's security. Furthermore, we point out findings which are unrelated to security.

7.1 Allowance For Ethena Minter May Not Be Consumed

(Informational)(Version 7)(Acknowledged

CS-SPRKALM-010

The integration with Ethena minter for USDe minting and burning requires external parties' (delegated signers, Ethena minter and redeemer) actions. The relayer can only trigger the approve() from the ALMProxy and expect the consecutive actions will be completed by the external parties.

In the following cases the allowance may not be fully consumed:

- The delegated signers sign orders with smaller volume which do not consume all the allowance.
- The Ethena minter or redeemer refuse to submit the order, which blocks the minting or redeeming and does not consume the allowance.
- The expected minting and burning may not be executed successfully due to the restrictions on Ethena minter such as the volume exceeds per block limit.

Consequently, the actual amount used in the interactions may be less than the amount tracked by the rate limit.

Acknowledged:

SparkDAO acknowledged the issue and decide not to change the code.

7.2 Withdraw From Aave Can Be Blocked By LTV=0 Asset

Informational Version 7 Acknowledged

CS-SPRKALM-011

When an asset is deposited under a user for the first time, the asset will be automatically configured as collateral if its LTV is non-zero and it is not in isolation mode.

In case a user has an asset enabled as collateral which has LTV==0, the user will not be able to withdraw any other assets that has LTV>0.

As a consequence, the following theoretical attack is possible:

- An attacker observed an asset that has LTV>0 is going to be configured to LTV==0 on Aave.
- It can supply on behalf of the ALMProxy (or send directly) a dust amount of this aToken.
- After the parameter change on Aave, the asset has LTV==0. The attacker successfully DoS the ALMProxy, which will not be able to withdraw the desired aToken (i.e. aUSDS, aUSDC...) from Aave.

Note that there is no rate limit and token restriction on function withdrawAave(). The relayer can withdraw the fully balance of the asset with LTV==0, which resets the usingAsCollateral flag to false and recovers the ALMProxy from the DoS.

Acknowledged:

SparkDAO has acknowledged this issue and stated a rate limit for the LTV=0 asset will be added to withdraw this asset in case this attack happens.

7.3 Gas Optimizations

Informational Version 1 Code Partially Corrected

CS-SPRKALM-004

In the MainnetController's swapUSDSToUSDC and swapUSDCToUSDS functions, to18ConversionFactor is always queried. However, the factor is expected to be a constant and could be made an immutable.

In (Version 7) of the MainnetController:

- The susds immutable is no longer needed as the SUSDS related logic are replaced by the general ERC-4626 integration logic.
- The Aave V3 POOL is queried every time from the input aToken. Since all the aTokens share the same pool, it can be set as an immutable in the constructor.

Code partially corrected:

The conversion factor has been set as an immutable in the constructor. In Version 8 the susds immutable has been removed.

8 Notes

We leverage this section to highlight further findings that are not necessarily issues. The mentioned topics serve to clarify or support the report, but do not require an immediate modification inside the project. Instead, they should raise awareness in order to improve the overall understanding.

8.1 A Compromised Ethena Minter Or Redeemer May Execute A Bad Order

Note Version 1

Ethena's minter and redeemer are two crucial roles that can submit the signed orders to the Ethena minting contract. Since the delegated signers are only semi-trusted and can be malicious, the minter and redeemer are fully trusted to never submit bad orders signed by the malicious delegated signers (also described in Roles & Trust Model).

In the worst case if Ethena' minter or redeemer are compromised, they may collude with a malicious delegated signer to execute an order with bad quote that drains the approved USDC from ALMProxy.

8.2 Aave Interprets Uint256 Max Withdrawal as Full Withdrawal

Note Version 7

Relayers should be aware that Aave will interprets a withdrawal with type(uint256).max amount as a full withdrawal with user's balance. Relayers should be careful of this special behavior if they are dependent on the input amount.

8.3 Special Cases Handling

Note Version 1

The ALM's functionality can be extended by allowing new controllers. Some currently unresolvable scenarios, could be resolved in the future if needed. For example:

- 1. Assume it is desired that for an L2, all funds are bridged back to mainnet. However, in case the PSM3 never holds sufficient USDC to bridge back to L1, funds will remain on L2. As a result, another controller could be whitelisted that initiates redeeming the PSM shares against the other two assets to then bridge them back to mainnet through the respective bridges.
- 2. The mint recipient for CCTP could be blacklisted. That effectively could DoS the USDC bridging. In that case, a new controller could be added that allows calling CCTP's replaceDepositForBurn to resolve the issue.

Ultimately, some unlikely (and intentionally unhandled) issues may arise with the existing controllers. To resolve such issues, new controllers can be added.
